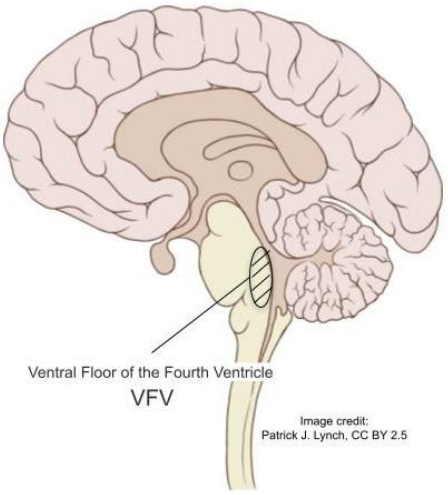
Abstract

The "hard problem of consciousness"—specifically the question of "where" and "how" qualia are generated—remains without a definitive answer. While information processing models centered on the cerebral cortex dominate current neuroscience, the physical conditions necessary for the emergence of the "feeling itself" (the raw quality of experience) remain elusive, regardless of how refined the descriptions of computation or mental representation become.



This paper posits that the persistence of this problem is largely due to a structural bias in research, which has focused disproportionately on the cortex because of its relative accessibility for measurement and analysis. Instead, this study directs its attention toward the Ventral Fourth Ventricle field (VFV)—a region where the brainstem reticular formation and cerebrospinal fluid (CSF) are in close proximity—as the central locus of qualia generation.

The VFV is a region characterized by a unique physical environment within the brain, where the reticular formation, astrocytes, ependymal cells, and CSF function as an integrated unit. While deeply involved in arousal control, multisensory input, and autonomic functions, the VFV provides the specific conditions required for qualia to emerge. The present hypothesis (the VFV Hypothesis) proposes that qualia are not the result of high-level cortical computation, but rather a physical "field state" established through the superposition of multisensory information within a unified spatiotemporal cross-section in the brainstem.

In the following sections, I will present the structural and evolutionary evidence supporting the VFV as the seat of qualia generation, and discuss the mechanism of its formation, the physical significance of the "cross-section" concept, and its functional roles in biological systems.

---

1. Theoretical and Structural Grounds for Qualia Generation in the VFV

Reasons for identifying the VFV as the locus of qualia generation converge into its anatomical specificity, evolutionary conservation, the consistency of its physical environment, its characteristic responses to anesthesia, and its alignment with clinical anomalies.

● **Physical Convergence of Multisensory Information:**
Sensory data essential for qualia—including visual, auditory, somatosensory, olfactory, and gustatory information—converge into the brainstem reticular formation through direct or indirect neural pathways. The VFV acts as the physical intersection for all such data, providing an environment where disparate sensory signals flow into a single region and physically overlap. The seemingly stochastic or "disordered" activity of the reticular formation is, in fact, a "meaningful superposition state" where multiple independent sensory streams overlap topologically. This state constitutes the physical foundation that allows fragmented information to coalesce into a single, integrated experience (qualia).

● **A Unique Physical Environment (The Unified Field):**
The VFV is the only region in the brain where four critical elements—dense reticular neurons, astrocytes, ependymal cells, and cerebrospinal fluid (CSF)—exist in such close physical proximity. In this region, neurons are relatively sparsely distributed and immersed in a broad extracellular fluid (ionic solution). This configuration facilitates the free formation of collective phase states of electrons and ions, allowing the region to function as a physically, electrically, and chemically continuous "unified field."

● **Anatomical Structure and the Unity of Consciousness:**
While most major brain structures, such as the cerebral cortex and cerebellum, are bilateral (paired) structures, the brainstem is a singular structure situated on the midline. The fact that our subjective conscious experience (qualia) is always "unitary" and does not fragment strongly suggests that its source is not the bilaterally divided cortex, but rather the physically singular and integrated field of the VFV.

● **Differential Responses of Qualia Under Anesthesia:**
Depending on the site of action of an anesthetic, qualia exhibit three distinct patterns of response:

- **Disruption of the CSF Environment (Field):** When general anesthesia disrupts the ionic environment or the synchronization conditions of the electric field in the CSF, the

"field" itself fails to form, resulting in the immediate disappearance of qualia and a disconnection of consciousness.

- **Inhibition of Sensory Input (Information):** When specific neurons surrounding the reticular formation are suppressed, the "content" of qualia may be altered or omitted, yet the state of arousal is maintained.
- **Paralysis of the Cerebral Cortex (Data Processing):** Even if the cortex is suppressed, as long as the conditions for generation in the VFV remain intact, the "raw feeling" of existence persists, albeit with an altered qualitative character.

● **Consistency with Clinical Anomalies:**
The VFV hypothesis provides a robust framework for elucidating clinical phenomena that are difficult to explain via cortex-centric models:

1. **Hydranencephaly (Consciousness without a Cortex):** Patients born with the majority of their cerebral cortex absent have been observed to exhibit emotional responses and signs of qualia, such as pleasure or distress. Under this hypothesis, while the cortex handles high-resolution sensory data processing, the VFV serves as the primary physical substrate for the "qualitative state (qualia)." Thus, as long as the VFV is functional, the fundamental mechanism of qualia generation operates independently of cortical input.
2. **Split-Brain (Unity of the Self):** Despite the surgical severance of the corpus callosum dividing the cortex into two hemispheres, the sense of a unified self does not split. This is because information from the bilateral cortex (upstream) is ultimately collected physically at the singular midline region of the VFV (downstream).

   Even if there are two sites of computational processing, the experience is physically necessitated to be integrated as long as it is received by a single "field."

---

2. The Mechanism of Qualia Generation

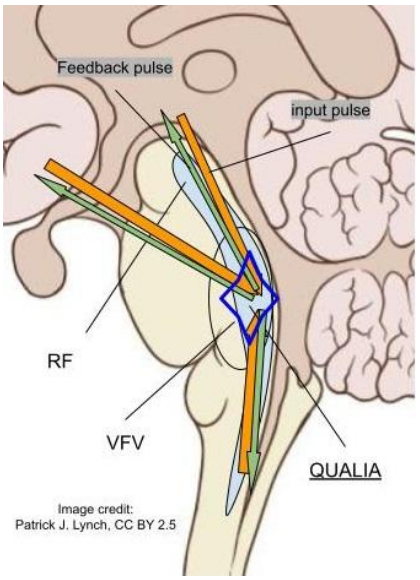
The following section details a hypothesized model of the physical and structural mechanisms of qualia generation centered on the VFV, traced along the sequential flow of information. While this sequence is derived from established anatomical and physiological data, it is presented here as a theoretical framework that identifies the most plausible conditions for qualia emergence within the scope of current scientific knowledge.

① Convergence of Information from Peripheral Organs and the Cortex to the Reticular Formation
Direct inputs from peripheral sensory organs, alongside detailed "digital" data processed in the cerebral cortex (such as "form," "sound," and "meaning"), converge at the reticular formation as the "raw materials" for qualia. Information regarding cortical activity, synchronization timing, and attention is funneled through the reticular transmission pathways to a single focal point

surrounding the VFV—an extremely compact physical region. Consequently, all essential information from the body and the brain required for qualia generation is delivered to the VFV.

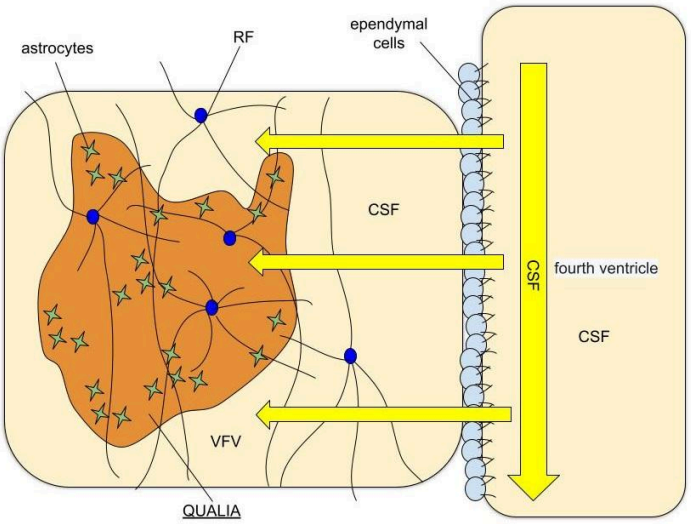
② Transmission from the Reticular Formation to Astrocytes (Digital-to-Analog Conversion)

When neurons within the reticular formation surrounding the VFV fire (spikes), they release potassium ions (K^+) and neurotransmitters into the extracellular space. Astrocytes immediately sequester these substances, triggering internal calcium waves (Ca^{2+}). In this process, the millisecond-scale, intermittent "digital signals (pulses)" derived from neurons are physically translated into persistent "analog signals (chemical waves)" within the astrocytes, lasting from hundreds of milliseconds to several seconds.



③ Expansion from Astrocytes to Cerebrospinal Fluid (Formation of a Broad Field)

Upon receiving analog information, astrocytes actively redistribute ions such as potassium (K^+) and sodium (Na^+) based on their internal states, thereby modulating the surrounding environment. This ionic flux is not merely a local phenomenon; it directly modulates the electric potential gradients and charge densities of the entire volume of the adjacent cerebrospinal fluid (CSF).



④ Emergence of Qualia within the CSF (Cross-sectional Formation)

The CSF acts as a "vast pool" that is electrically and chemically continuous with the brain parenchyma. Within the liquid field of the VFV, disparate sensory signals (represented by ionic densities and rarefactions), such as vision and audition, physically intermingle to form a single integrated state. The "two-dimensional cross-sectional structure" of electrons and ions that arises at this precise moment constitutes the physical entity of the qualia we experience.

⑤ Feedback from Qualia (CSF) to Astrocytes

The state of the physical "field" formed within the CSF (the synchronization patterns of electrons and ions) exerts a dynamic feedback influence back onto the astrocytes. The astrocytes receive these field fluctuations from the CSF as changes in membrane potential and charge distribution.

⑥ **Action from Astrocytes to the Reticular Formation**
Based on the "field state" fed back from the CSF, astrocytes finely tune the membrane potentials and firing thresholds of nearby reticular neurons. During this interaction, "neuronal traces" (patterns of firing and synaptic biases) are engraved into the reticular neurons as a physical consequence of the process.

⑦ **Distribution from the Reticular Formation back to the Cortex and Other Regions**
While the qualia generated in the VFV exist physically as a singular, indivisible "cross-section," their influence is returned to various organs as "projections"—signals partitioned into formats processable by each recipient. The roles of these projections, derived from the unified qualia event, are as follows:

- **Projections to the Cerebral Cortex:** These serve as "status tags" to lock vast amounts of digital computation into a single "meaningful experience." Since the cortex retains detailed data, these projections only provide the synchronization conditions and constraints necessary to "confirm the current state as reality."
- **Projections to the Limbic System (e.g., Amygdala):** These are "value tags" essential for survival, determining whether an event is "dangerous or safe" or "pleasant or unpleasant," with the structural details of the experience stripped away. This allows for emotional weighting without waiting for complex semantic analysis.
- **Projections to the Autonomic Nervous System and Somatic Regions:** These function as "tone modulation signals" to instantaneously coordinate muscle tension, heart rate, posture, and reflex actions across the entire body.

In this manner, the rich qualia cross-section generated in the reticular formation is distributed as extremely low-bandwidth, "shadow-like" signals containing only the components necessary for each system. By receiving these specific projections (traces), each organ prevents information overload while ensuring that the entire brain shares a consistent "state of the present moment." The cortex synchronizes these thin projections with its own high-resolution digital processing, ultimately achieving the "determination of information" accompanied by subjective certainty.

---

3. The Physical and Structural Significance of Qualia as a "Cross-section"

The concept of qualia as a "cross-section" is not a mere metaphorical device; it refers to the physical superposition (superimposition) of information within the VFV.

- **Physical Superposition of Multisensory Information:**
  Sensory information from the five senses—such as vision, audition, and somatosensation—is physically superimposed within the same spatiotemporal window in the brainstem reticular formation. In this process, the critical factor is not the discrete

digital firing (spike signals) of individual neurons, but rather the collective state of electron and ion populations that these neurons generate within the extracellular fluid and the cerebrospinal fluid (CSF).

- **A Two-Dimensional Structure within a Three-Dimensional Space:**
  Within the three-dimensional physical space of the brainstem, a state in which the phases and synchronization patterns of electron populations align emerges as a "two-dimensional cross-sectional structure." This cross-section itself is the physical reality of the qualia we subjectively experience, such as the "redness" of a color or the "sensation" of pain.
- **Formation of an Analog "Field":**
  Astrocytes interpret the coarse digital signals from neurons and convert them into a smooth, continuous state by regulating the ionic environment. This integrates noisy neural activity into a "clean" and "high-definition" cross-section of qualia.
- **Correspondence Between Qualia and Neurons, and the Generation of Traces:**
  Qualia are physical cross-sectional phenomena formed by electrons and ions within the VFV. The physical interactions occurring during this generation process simultaneously engrave "neuronal traces"—such as specific firing patterns and changes in synaptic plasticity—into the surrounding neurons. Consequently, qualia and neuronal traces are generated in a state of physical alignment. Qualia themselves do not directly control behavior; rather, they influence actions and judgments through the medium of these traces.
- **The Physical Basis of Subjective Causality (Psychophysical Simultaneity):**
  Physiologically, the body is driven by material "neuronal traces" (signals). However, the crucial point is that these traces are generated in a "physically simultaneous and isomorphic" correspondence with the formation of the qualia cross-section. Because the qualia (experience) and the trace (command) exist inseparably as two sides of the same physical phenomenon, an indubitable subjective sense that "my will (qualia) determined my action" inevitably arises. This is not a mere illusion, but a structural consequence of the VFV system.
- **Return as Status Tags:**
  The generated traces are returned to the cerebral cortex and the autonomic nervous system as "status tags." This allows the cortex to receive constraints and priorities—such as "what is important now" and "how to act"—directly from the qualia state, without the need for exhaustive computational processing.

---

4. The Functional Roles of Qualia

The generation of the qualia cross-section by biological organisms provides decisive advantages for survival.

- **Physical Shortcut:**
  While high-level information processing (digital computation) in the cerebral cortex is time-consuming, qualia generation in the VFV functions as a "physical shortcut" to enable timely decision-making.
- **Model Stabilization (World-Locking):**
  The cortex continuously maintains multiple candidate interpretations of its environment. Qualia "lock" these interpretations into a single state—declaring, "This is the current reality." This stabilized cross-sectional state instantaneously dictates the direction of behavior.
- **Value Attribution:**
  By bundling mere sequences of information into a single, unified experience imbued with "personal value" (such as danger, pleasure, or discomfort), the entire system can be immediately oriented toward specific actions.
- **Attention:**
  Through the mechanism of attention, the complex overlaps of electronic states in the reticular formation are "unraveled," allowing specific patterns to be selected and concentrated into a stable cross-section. This enables the instantaneous, low-cost filtering of the most vital "here and now" information from vast amounts of parallel data.
- **Memory Selection:**
  During the qualia generation process, multisensory information is screened based on "value and importance parameters." Only specific states that have been attended to are engraved as "neuronal traces" in the cortex and hippocampus. This ensures that essential content is preferentially fixed from the vast pool of incoming information.

---

5. Conclusion

This paper has described the locus and fundamental principles of qualia generation within the Ventral Fourth Ventricle field (VFV). Subsequent reports will successively address the ontological identity of the subjective observer within this hypothesis, the physical verifiability of qualia, and the specific details regarding information modulation protocols in the reticular activating system.
